Attention: Document Control Officer

Dear Sir or Madam:

EPA Case Number P-08-509

On behalf of E. I. du Pont de Nemours and Company, I am pleased to enclose a new test study. A Pilot Reproduction Study with the Northern Bobwhite Quail, Colinus virginianus, in connection with EPA Case Number P-08-509.

If there are any questions, please call Jane Bradd Andersen at 302-999-2377.

Very truly yours,

Donna C. Laudisi

ECOTOXICOLOGY AND ENVIRONMENTAL FATE

March 11, 2010

[REDACTED]
E.I. du Pont de Nemours and Company
Wilmington, Delaware 19898

RE: Report: DuPont [REDACTED]

Dear [REDACTED]

The following is a summary of the findings for the study: [REDACTED] A Pilot Reproduction Study with the Northern Bobwhite Quail, *Colinus virginianus* (Wildlife International Ltd. Project No.: [REDACTED])

The study evaluated the effects upon adult northern bobwhite quail of dietary exposure to [REDACTED] over a six-week period. Effects on health, weight gain and feed consumption were examined. In addition, the effects of adult exposure to [REDACTED] on the number of eggs laid, normal development of eggs, viability of the embryos, percent hatchability, offspring survival and egg shell thickness were evaluated.

Three treatment groups, each containing five pairs of northern bobwhite quail, were fed diets containing [REDACTED] at nominal dietary concentrations of 10, 100 or 1000 ppm. A fourth control group, fed non-treated diet, was maintained concurrently with the treatment groups.

METHODS

Test diets were prepared by mixing [REDACTED] into a premix that was used for weekly preparation of the final diet. Homogeneity of the test substance in the diet was evaluated by collecting six samples from each of the 10 and 1000 ppm treated diets and one sample from the control diet on Day 0 of Week 1. Samples also were collected from the 100 ppm treated diet on Day 0 of Week 1, and from the control and all treatment group diets during Week 6 of the test to measure/verify test concentrations. Additionally, control and treatment group diet samples were collected from the trough feeders on Day 7 of Week 1 to assess stability of the test substance under actual test conditions.

The test birds were acclimated to the facilities and study pens prior to initiation of the test. During the study, all adult birds were observed daily for signs of toxicity or abnormal behavior. A record was maintained of all clinical observations. Adult body weights were measured at test initiation, on Weeks 2, 4, and at adult termination. Feed consumption for each pen was measured weekly throughout the test. At the conclusion of the exposure period, all adult birds were euthanized and necropsied.

Eggs were collected daily from all pens, when available. During Weeks 1 and 2 eggs were counted, then disposed. Eggs produced during Weeks 3 through 6 were counted and those selected for egg shell thickness measurement were removed. The remaining eggs were identified by an alphabetic lot

March 11, 2010
E.I. du Pont de Nemours and Company
Page 2

code (Lots A, B, C & D). All eggs laid in a weekly interval were considered as one lot. All remaining eggs were candled to detect egg shell cracks or internal abnormalities. Cracked or abnormal eggs were recorded and discarded. All eggs not discarded were placed in an incubator. Eggs were candled on Day 12 of incubation to determine embryo viability and on Day 21 to determine embryo survival. On Day 21 of incubation, the eggs were placed in a hatcher and allowed to hatch. All hatchlings, unhatched eggs and egg shells were removed from the hatcher on Day 25 or 26 of incubation. The individual body weight of the surviving hatchlings was determined. Hatchlings were leg banded for identification by pen of origin and then routinely housed according to the appropriate parental concentration grouping in brooding pens until 14 days of age. Offspring were observed daily from hatching until 14 days of age. At 14 days of age, the average body weight by parental pen of all surviving offspring was determined.

All eggs laid during the six-week test were used in evaluation of egg production among the test groups. The evaluations of the other reproductive parameters were based on the eggs produced during Weeks 3 through 6 of the test (Lots A – D).

RESULTS

Mortalities and Clinical Observations

No mortalities occurred during the course of the study. Incidental clinical observations normally associated with penwear were observed during the test. Such observations included foot and head lesions and an ocular injury. Except for the incidental clinical findings, all birds in the 0, 10, 100, or 1000 ppm treatment groups were normal in appearance and behavior for the duration of the test. Daily clinical observations are presented in Appendix XI.

Body Weight and Feed Consumption

When compared to the control group, there were no apparent treatment-related effects upon body weight at the 10, 100 or 1000 ppm test concentrations at any body weight interval. Mean body weight measurements are presented in Table 1. Individual body weight measurements are presented in Appendix I.

When compared to the control group, there appeared to be no treatment-related effects upon feed consumption at the 10, 100 or 1000 ppm test concentrations at any feed consumption interval. Mean feed consumption measurements are shown in Table 2. Feed consumption measurements by pen are presented in Appendix II.

Reproductive Results

Due to the small sample size and short length of range-finding tests, it is not atypical for variation in egg production to be observed. While reproductive parameters were variable among individuals, when compared to the control group, there appeared to be no treatment-related effects upon reproductive performance at the 10 or 100 ppm test concentrations. However, at the 1000 ppm test concentration there was a slight reduction in viability of embryos, which was also evidenced in reductions in numbers of hatchlings and 14-day old survivors as percentages of eggs set and the maximum set. Summaries of the reproductive data are presented in Table 3. Reproductive parameters by pen are presented in Appendices III, IV and V.

Egg Shell Thickness Measurements

When compared to the control group, there appeared to be no treatment-related effects upon egg shell thickness measurements at the 10, 100 or 1000 ppm test concentrations. Egg shell thickness measurement data are presented in Table 5 and Appendix VI.

Offspring Body Weights

When compared to the control group, there appeared to be no treatment-related effects upon offspring body weights at the 10, 100 or 1000 ppm test concentrations. Offspring body weight data are presented in Table 6 and Appendices VII and VIII.

Gross Necropsy

At the end of Week 6 (Day 42), all surviving birds were euthanized and subjected to gross necropsy. All findings observed were considered to be incidental and not related to treatment. Necropsy data, summarized by treatment group, are presented in Table 7. Individual necropsy findings are reported in Appendix IX.

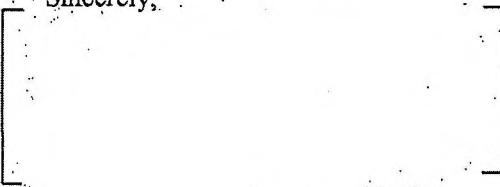

Analytical Chemistry

Homogeneity of the test substance in the diet was evaluated by collecting six samples each from the 10 and 1000 ppm treatment group diets on Day 0 of Week 1. Additionally on Day 0, two samples were collected from the 100 ppm treatment group to verify test substance concentration in the diet. Two samples were collected from the feeders for each of the treatment concentrations on Day 7 of Week 1 to verify the presence of the test substance under actual test conditions. Additional verification samples, two each from the 10, 100 and 1000 ppm treatment groups, were collected on Day 0 of Week 6. Results of the analysis of the diet samples verified that the test substance was present at the appropriate concentrations, that the diet mixes were homogeneous and that the test substance was stable for the length of exposure. Results of the analysis of the diet samples are presented in Appendix X.

Conclusion

Northern bobwhite quail were exposed to [] at dietary concentrations of 0, 10, 100 and 1000 ppm over a six-week period. There were no treatment-related mortalities, overt signs of toxicity or treatment-related effects upon body weight or feed consumption at any of the test concentrations. Additionally, there were no treatment-related effects upon any of the reproductive parameters measured at the 10 or 100 ppm test concentrations. At the 1000 ppm test concentration there were slight reductions in viability of embryos, and reductions in numbers of hatchlings and 14-day old survivors as percentages of eggs set and maximum set that were likely treatment related. The no-observed-effect concentration for northern bobwhite quail exposed to [] in the diet during the study was 100 ppm.

Sincerely,

[]
